Short answer: **yes—after a deep dive on the new "Gemini 2.5 Pro" analysis, I'm making a few targeted edits** to the Event Horizon Fund to better align with the places of **maximum, durable scarcity** it highlights (power, WFE, and EDA), while keeping risk capped (15% max per name) and Moonshot at 10%. The changes are incremental—**not a wholesale rewrite**—but they tilt the portfolio toward the **most non-substitutable bottlenecks** and adopt Gemini's evidence where it's strongest.

What in Gemini changed my mind (and what didn't)

Stronger conviction to up-weight:

- **Energy (Power) as the terminal bottleneck.** The paper's "Power Wall" framing (AI DC power demand ~108% CAGR through 2030) reinforces that **existing nuclear baseload** should be repriced as strategic infrastructure. I'm moving **PWR back to 3%** (from 2%) alongside a max-weight **CEG at 15%**. Net sleeve **18%**.

- **WFE (the factories that build the factories).** I'm taking WFE to **12%** by lifting **AMAT to 4%** (ASML stays 8%). This reflects the "geopolitical multiplier" and long orderbooks that run **through** any foundry cycle.

- **EDA (the digital blueprints).** I'm raising **SNPS to 5%** to capture the "custom-silicon multiplier" and recurring, high-margin toll-road characteristics.

- **Networking reality check.** The analysis documents NVIDIA's Spectrum-X rise and an emerging Ethernet **duopoly** dynamic; keeping **ANET at 5%** (trimmed from 6% in V6) remains appropriate.

Where I agree but won't fully match Gemini's sizing (yet):

- **Rack-scale & Integration (DELL/VRT).** I'm **keeping it concentrated in the two winners (VRT, DELL)**, but I will **not** push the sleeve to 15% right now. DELL's AI server backlog is massive, but its **margin conversion cadence** is still the watch-item; I'll hold a stout **13%** and scale on clean backlog-to-revenue proof.

- **Security (CRWD) and Defense (AVAV/KTOS).** I accept the theses (AI-native security demand is non-discretionary, and "affordable mass" is getting formalized—e.g., USMC's Valkyrie path). For now, I **leave CRWD at 2%** and the **defense sleeve at 2%** (1% each) because these are not the **rate-limiting** bottlenecks on total AI capacity; I'll expand on triggers (below).

- **Accelerators (NVDA/AVGO).** Gemini nudges NVDA up to 8% and total sleeve to 11%. I'm **keeping total at 9%** for now (NVDA 6%, AVGO 3%) to fund higher-conviction upstream bottlenecks (power/WFE/EDA). It's a tradeoff: we still own the platform leader and custom-silicon enabler, but concentrate the incremental dollar where scarcity is hardest.

Note on arithmetic: Gemini's V7.1 tally **over-allocates** (core ~96% **plus** Moonshot 10% = 106%). I've normalized to **90% core + 10% Moonshot = 100%** while still adopting its strongest tilts.

Updated allocation (V7.2) — changes in bold

Core (90%)

- **Energy / Power (18%)** → **CEG 15%**, **PWR 3%** (**PWR +1%**)
- **Foundry & Adv. Packaging (12%)** → **TSM 12%** (unchanged)
- **WFE / Semi Cap Equipment (12%)** → **ASML 8%**, **AMAT 4%** (**AMAT +1%**)
- **Rack-Scale Integration & Liquid Cooling (13%)** → **VRT 8%**, **DELL 5%** (keep concentrated; hold below Gemini's 15% pending margin proof)
- **Accelerators & Custom Silicon (9%)** → **NVDA 6%**, **AVGO 3%** (**–1% total**)
- **HBM / Memory (6%)** → **MU 6%** (**–1%**)
- **EDA Software (5%)** → **SNPS 5%** (**+1%**)
- **AI Data Center Fabric (5%)** → **ANET 5%** (unchanged vs prior V7, already trimmed vs V6)
- **AI-Native Security (2%)** → **CRWD 2%** (hold; see triggers)
- **AI-Native Operate & Control (2%)** → **PLTR 2%** (kept at Gemini's level)

- **AI-Enabled Military (2%)** → **AVAV 1%**, **KTOS 1%** (retain base exposure; see triggers)

- **Bio-Risk Insurance (1%)** → **MRNA 1%** (hedge)

- **Strategic Materials (3%)** → **MP 3%** (hedge retained)

Moonshot sleeve (10%) — unchanged: **INTC (3.5%), CORZ/IREN/APLD (3.5%), KTOS (2.0%), MRNA (1.0%)**, via LEAP call spreads / defined-risk structures.

Net edits vs my prior "Final Proposed":
+1% **Energy** (to 18), +1% **WFE** (to 12), +1% **EDA** (to 5), **–1% HBM** (to 6), **–1% Accelerators** (to 9). Everything else unchanged or reaffirmed.

Why these edits improve expected return (under AI-2027)

- **Return capture: bottlenecks > platforms.** Gemini's synthesis makes a compelling case that **pricing power accrues most persistently to the scarcest inputs**—power, EUV tools, and EDA capacity—rather than the end-product accelerators, where competition and gross-margin gravity intensify over time. Re-weighting toward **CEG/ASML/AMAT/SNPS** raises the portfolio's exposure to the **non-substitutable chokepoints** that all buyers must pay up for.

- **Risk efficiency:** We already consolidated to **VRT + DELL** in rack-scale and **ANET only** in fabric, as Gemini recommended; keeping those sleeves sized **below** Gemini's maximum proposal creates dry powder if/when **conversion to revenue** (DELL) or **duopoly dynamics** (ANET vs Spectrum-X) break decisively in our favor.

- **Portfolio arithmetic discipline:** Normalized to **90/10 core/Moonshot**, while still implementing the strongest tilts (Energy, WFE, EDA). Gemini's table over-allocated; I fixed that and preserved the thesis.

Where I intentionally diverge from Gemini's sizes (for now)

- **CRWD at 2% (vs 3%).** I agree AI-security spend is non-discretionary, but it's **not a build-rate limiter** like power or HBM. We keep exposure, with a **clear add-trigger**: if CRWD's ARR growth sustains **>25% YoY** for two more prints (and operating leverage holds), I'll lift to **3%** by trimming **Accelerators** another 1%.

- **Defense at 2% (vs 3%).** The USMC's movement on **Valkyrie** is a major validation, but award timing and production cadence remain the swing factors. Baseline stays **1% AVAV / 1% KTOS**, with upside largely via the **Moonshot KTOS calls**. I'll raise to **3%** if Valkyrie funding ramps into multi-year budget lines **and** KTOS/AVAV disclose firm multi-year production awards.

- **Rack-scale at 13% (vs 15%)** and **DELL at 5% (vs 7%).** DELL's backlog/guide support Gemini's enthusiasm, but I want **a bit more proof on ISG margins** during backlog conversion. Trigger: if DELL achieves **>$18B AI server shipments in FY26 and** keeps ISG op margin **≥9%**, I'll boost DELL to **6–7%** (rack-scale 14–15%) funded from **Accelerators**.

- **Accelerators at 9% (vs 11%).** We still own NVDA/AVGO meaningfully, but the extra 1–2% of capital works harder upstream (CEG/WFE/EDA) in this scarcity regime. I'll revisit if NVDA's **platform share** holds firm against custom ASICs for two consecutive product cycles **and** unit economics remain >historical levels.

Actionable "raise/trim" triggers I'm adopting from Gemini's dashboard

- **CEG – maintain 15%, add on pullbacks:** New ≥500MW tech PPA at premium pricing by mid-2026 → **confirm thesis**. Trim only if a scalable >100-hour storage breakthrough **commercializes pre-2028**.

- **ASML – hold 8%:** High-NA EUV production/installs tracking; backlog robust → **hold/raise** on weakness.

- **VRT – hold 8%:** Two of top-3 hyperscalers publicly guide to **>50%** of new AI racks liquid-cooled by 2027 → **confirm 8%**; trim if a competitor consistently wins most large deployments for ≥2 quarters.

- **DELL – candidate to raise:** Backlog-to-revenue **>$18B FY26** and ISG margin **≥9%** → **raise DELL by +1–2%**.
- **ANET – hold 5%:** If Spectrum-X momentum stalls (market share re-expands in ANET's favor), consider **+1%** funded from **Accelerators**.
- **CRWD – raise trigger:** Two more quarters >25% ARR growth with stable unit economics → **+1%** (to 3%).
- **AVAV/KTOS – raise trigger:** Program-of-record funding + firm production schedules → **+1%** (to 3% total).

Bottom line

- I **adopt** Gemini's biggest upgrades—**Energy↑, WFE↑, EDA↑**—and **keep** our prior consolidations (VRT/DELL only; ANET only; removed AMD/ARM/MRVL/HPE/FLEX/NVT/VST).
- I **normalize** sizing to 90% core + 10% Moonshot, and **defer** Gemini's extra 1–3% in Security/Defense/Rack-scale until **explicit triggers** hit.
- Net result: **V7.2** is a tighter, higher-conviction portfolio that should **incrementally improve expected returns** under AI-2027 by leaning even harder into the **hardest bottlenecks**—while keeping flexibility to scale the rest as the evidence arrives.

If you want a more aggressive "Gemini-max" variant right now (i.e., **CRWD 3%, DELL 7%, AVAV/KTOS 1.5% each**), we can do that by trimming **Accelerators –1%** and **Rack-scale –1%** today; I held those in reserve to keep the **power/WFE/EDA** upgrades fully funded without overtightening elsewhere.
